II. The Tests of Combined Treatment of Botulism Intoxica-
tion with Antibiotics and Antibotuline Serum.

Orig Pub : Tr. kharkovsk. n. I. in-ta, vaccin i syvorotok, 1956, 23,
35-42

Abstract : 1-2 DL_m of botulin toxin were injected intravenously into
mice and in 15 minutes to 8 hours 0.8-1/6 mg of biomycline,
0.3 mg of sanzine, 0.6 mg levomycetine were administered.
A satisfactory therapeutic effect was obtained.
The effect of antibiotics was increased if antibotulism
serum was added.

AUTHORS: Derkach, V. P., Katkov, P. A.

TITLE: ~~An Instrument~~ for the Visual Observation of the Amplitude Characteristics (Pribor dlya vizual'nogo nablyudeniya amplitudnykh kharakteristik)

PERIODICAL: Pribery i tekhnika eksperimenta, 1958, Nr 6, pp 111-112 (USSR)

ABSTRACT: The circuit of the instrument is shown in Fig.1. The first three tubes of the circuit form a rectangular pulse generator; the first tube is connected in a blocking oscillator circuit which produces narrow pulses; these are applied to the grid of the second tube and hence, after inversion and amplification, to the grid of the third tube; narrow rectangular pulses of positive polarity are obtained at the output of the third tube. The pulses are applied to the control grid of a pentode whose suppressor grid is supplied with a sawtooth voltage. This waveform modulates the amplitude of the pulses. The negative amplitude-modulated rectangular pulses from the anode of the pentode are applied to an amplifier tube, where they are inverted; from the anode of this tube, the pulses are fed to the input of a cathode follower which acts as a source of amplitude-modulated pulses. The

Card 1/2

An Instrument for the Visual Observation of the Amplitude Characteristics

resulting signal can be applied to an investigated device; the output pulses of this device are applied to the vertical plates of an oscillograph whose horizontal plates are actuated by the same sawtooth voltage which modulates the pulse amplitude. The instrument proved successful in operation and was found useful in the measurement of the modulated non-linearities. The paper contains 1 figure.

TITLE: Tube With Successive Beam Splitting

PERIODICAL: Priborostroyeniye, 1961, No. 1, pp. 1 - 3

TEXT: A new electron-beam memory with successive splitting of the beam was developed at the Vychislitel'nyy tsentr AN USSR (Computation Center of the AS UkrSSR). In this tube, the cathode emits a broad electron beam hitting four splitter plates. These plates constitute a fine grid produced from a dielectric. Metal layers are applied to the inner side of the fine slits (Fig. 1). 50% of these metal layers are electrically connected with an upper or a lower terminal. The first plate consists of one part and screens off half of the broad electron beam. The second plate consists of two parts, each of which screens off a quarter of the electron beam. The third plate consists of four parts, and the fourth plate consists of eight parts, each of them screening off one-sixteenth

Card 1/4

88997

Tube With Successive Beam Splitting

of the electron beam (Fig. 2). If N plates are available, it is possible, by a proper choice of potentials in the two halves of the plates, to obtain $(22N)$ memory cells by splitting the electron beam into two beams perpendicular to each other. This splitter-plate system causes the formation of a relief in the electron beam. The conditions for obtaining a relief and the adjustment of the relief after each computation process are studied.

Current density must be 20 microamperes per mm^2 . For a tube of $64 \cdot 64$ memory cells with an area of 1 mm^2 , the cathode area must be $12.8 \cdot 12.8 \text{ cm}$ to supply a current of about 165 milliamperes. To verify this method experimentally, a tube was designed which allows the signal to be directly observed on a screen. The tube contained a cylindrical cathode with a diameter of 30 mm, a system of splitter plates, a grid collector, and a target. The splitter plates consisted of 100μ thick high-quality mica. Their dimensions were $40 \cdot 40 \text{ mm}$. In the center of the plate, two $1 \times 20 \text{ mm}$, slits were punched out at a distance of 2 mm from one another and coated with conductors. Although experimental results were satisfactory, a number of mathematical and physical problems are still unsettled. The different

TEXT:

The above tubes have been described by the authors (Priborostroyeniye, no. 1, 1961; Avtomatika i priborostroyeniye, no. 3, 1960). It is found that the beam switching is slowed down owing to the capacity formed by a part of conducting slots of the gratings. In the worst case the switching time increase is proportional to the sum of two largest adjacent resistances, multiplied by the capacity due to 1/4 of slots in each electrode. This capacity is difficult to determine analytically; a method based on graphical representation of the field distribution is recommended, and examples are given. If there are no more than 1024 memory elements in the grating, millions of switch-Card 1/2 ① S/119/61/000/001/001/013

AUTHOR: Derkach, V. P.

TITLE: Cathode-ray tubes for the storage of binary information.

SOURCE: Voprosy vychislitel'noy tekhniki; mashiny, ustroystva, elementy i ikh primeneniye. Ed. by A. M. Novik. Kiyev, Gostekhizdat USSR, 1961, 74-89.

TEXT: The paper presents a functional analysis and extensive survey of existing literature on the functioning of cathode-ray tubes (CRT) used in modern digital electronic computers for the storage of binary information. The many types of CRTs employed in computers are classified and analyzed separately: (1) The ordinary oscillograph tube with a record derived from redistribution and charge-reversal counting. The advantage of this type of tube for the storage of information consists in their relatively low price (thanks to mass production) and their long service life attributable to the low ray fluxes. However, the small number of elementary cells, the low level of the output signal, the appreciable nonuniformity of the screen, and other shortcomings have impeded the adoption of this type of CRT in computer engineering. (2) The "potentialoscope" with barrier grid. CRTs of this type are relatively simple to manufacture, exhibit a simple control system for recording and read-out, have a greater information-storage capacity than the precedingly-described CRTs, and have an intense read-out signal. The selection of cells, as well as the differen-
Card 1/2

Cathode-ray tubes for the storage of

S/777/61/000/000/003/005

tiation in the recording of one binary signal from another, is done by a quantitative and not by a qualitative indication, which ensures a great dependability and accuracy of the machine. However, the operational potentialoscope is complicated by the need for a regular renewal of the recorded information. (3) Tube with a modulation of the ray flux by the recorded charges. Contrary to the afore-described CRTs for the reading of recorded binary bits, there is in this type of CRT no requirement for a direct contact between the electronic ray with the target element that stores the information. This permits the repeated reading of recorded information without re-recording. Literature data show that after 25,000 readings the signal intensity is reduced by only 1.5%. The manufacturing complexity is the most outstanding shortcoming of this CRT. Dependability data are not yet available. (4) Tube with a mosaic target and a cathode ray for the preservation of the potential relief. The principal advantage of this type of CRT is the unlimited storage life of binary information with any desired number of returns into the same unit. The shortcomings of this type of CRT are discussed in detail. (5) Graphechon. (6) Selectron. The mode of functioning of these last 2 types of CRT is described in detail. Current developments, particularly in the Selectron, are pointed out. There are 14 figures and 32 references (12 Russian-language Soviet and 20 English-language, of which 2 in Russian translation).

AUTHOR: Derkach, V.P.

TITLE: New method of selecting target cells in multibeam devices

SOURCE: Vychislitel'naya matematika i tekhnika; trudy aspirantov Instituta kibernetiki AN USSR. Izd-vo UkrSSR, 1962, 9-15

TOPIC TAGS: multibeam electron device, bifurcated-beam electron device

ABSTRACT: A method of consecutive bifurcation of the electron beam, suggested by V. M. Glushkov, Member of the AN UkrSSR, is described. The bifurcation is effected by two dividing packages that consist of thin flat electrodes. Each electrode is represented by metal-coated dielectric plates that form "slots". In the first-from-cathode electrode, the metal coats of one-half of the slots are connected to the upper terminal, the coats of the other half, to the lower terminal. By applying suitable potentials, initial bifurcation of the electron beam can be achieved. The next electrode is equipped with 4 equal groups of slots, the first and the third of them being connected to one terminal, and the second and the fourth, to the other. Hence, by applying a higher and a lower voltage to these terminals, the beam can be further bifurcated, and only one-quarter of the initial beam will

Card 1/2

L 11601-63

2

reach the electrode no. 3. The third electrode consists of 8 groups of slots, and so on. N inputs can control 2 sup N/2 memory cells; with 40 inputs, any of 1,048,576 addresses can be selected, which is about 100 times as much as in the selectron. Realization of the device with a hot cathode is considered inexpedient; an effective and uniform cold emitter is desirable. Potential distribution patterns were studied on an electrolytic simulator. Also a special 16-beam, boride-lanthanum-cathode, bifurcating-electrode experimental device was built and tested. Orig. art. has: 5 figures.

TITLE: Luminescent matrix for photorecording images produced by electronic
computers

SOURCE: Avtomatika i priborostroyeniye, no. 1, 1964, 28-31

TOPIC TAGS: luminescent matrix, computer, computer output, computer output,
photorecording, EL-510 phosphor, EL-460 phosphor

ABSTRACT: Experiments with recording the output information of computers on
luminescent 256 x 256-element plates ("matrices") and photographing it are
described. Each element is 0.5 x 0.5 mm, and the distance between elements is
0.5 mm. A line-by-line exposure is used to ensure higher speed and contrast of
the plates coated with EL-510 (green) and EL-460 (blue) phosphors.

Card 1/32

ACCESSION NR: AP4020313

Characteristic curves for two types of film are given. Symbol formation as shown in Enclosure 1 permits a recording rate of 700 symbols per sec; 21 lines, 40 symbols in each line, are used. The same plates permit the recording of drawings, sketches, etc. A nonlinear-resistance powder based on CdS can be used to increase the contrast of the plates. It is claimed that a plate treated with this powder can ensure a recording rate of 10,000 symbols/sec. Orig. art. has: 5 figures, 7 formulas, and 1 table.

TITLE: Accuracy of conversion of a binary code into voltage by combining currents

SOURCE: Avtomatyka, no. 5, 1964, 69-74

TOPIC TAGS: code voltage conversion, digital analog conversion

ABSTRACT: Errors are estimated in the process of conversion of a binary code into voltage by means of combining equal currents in a binary ladder network consisting of fixed resistors. An electron-tube switch with an improved current stabilization is considered. Various noise sources are evaluated quantitatively, and their effect on the output voltage is estimated. Some experimental verification is claimed. Orig. art. has: 6 figures and 16 formulas.

<p>CA</p> <p>The action of dyes on typhus neurovirus. V. S. Derkach and S. A. Blinkin. <i>Med. eksptl. (Ukraine)</i> 1939, No. 1, 22-30; <i>Chem. Zvez.</i> 1940, II, 1508.—An investigation was made of the effects of different dyes on the neurovirus of typhus. The basic aniline dyes of the malachite green group and rosaniline and pararosaniline deriva. were found to be most active. The strongest action was shown by brilliant green and gentian violet; Me violet was less active while basic and acid fuchsin were still less so. Thionine was completely inactive; the same was true of the oxidation product of methylene blue, Azure 2, while methylene blue itself was active. Bismark Brown, neutral red and safranin showed only weak bactericidal activity. The acid dyes, eosin and alizarin red, showed either very slight bactericidal activity or none whatever. M. G. Deep, prolonged sleep produced by urethan or medinal lowers to the resistance of white mice to exptl staphylococci and streptococci infections. Drugs that strengthen the excitability of the central nervous system (e. g., caffeine, strychnine) in certain dosages also increase this resistance. Sleep produced by medinal or urethan lowers the therapeutic effect of penicillin. Caffeine and strychnine increase the therapeutic action of penicillin. Clinical investigation based on these exptl data should be carried out.

"The Combined Action of Antibiotics on Dysentery Bacilli," V. S. Derkach, O. S. Belaya, A. M. Savchenko, F. A. Revis-Turchina

Zhur Mikro, Epid, i Immun, No 7, pp 33-35

Sonne bacilli are most resistant to synthomycin (I), sanazin (II) and gramicidin S (III), Grigor'yev - Shiga bacilli least resistant. Flexner bacilli occupy an intermediate position. Use of combinations I-III, I-II, and II-III in vitro increased the bactericidal effect on all groups of bacteria by factors 4-32-64-128. I and II in doses which protected 8-20% of white mice against virulent Sonne and Flexner cultures or did not give any protection were found to protect 64-71.6% of the mice when used together (I-II). On the basis of these findings, combinations of antibiotics were used with good results on children.

EXCERPTA MEDICA Sec 7 Vol. 11/8 Pediatrics Aug 57

2033. DERKACH V.S., BELAYA O.S., BULATSEN A.M., KHLOVNER S.I., GRINBERG G.I., KVIYAT K.M. and ZVYAGINTSEVA L.M. Dept. of Microbiol., Vaccine and Serum Inst., Khar'kov. *Long term results of combined antibiotic treatment of chronic dysentery in children (Russian text) VRAC.DELO 1956, 6 (571-575)

In 1952 Derkach and Belaya introduced a method of combined treatment of dysentery, with sintomycin (optically inactive chloramphenicol) and sanazin (synthetic preparation of pyocyanin). Evaluation and modification of the method continued during 1952-1954, and in all 356 children were observed. The dose administered was 1-1.5 g. sanazin to 8-13.0 g. sintomycin (depending on the age of the child). In the case of a prolonged illness or of persistent excretion of bacteria, a second course of treatment was given. Long-term results were obtained with combined therapy with sintomycin and sanazin in 328 children with chronic dysentery or carriers with ages ranging from 6 months to 5 years. One month after the end of the treatment only 9.4% of 265 carriers continued to excrete dysentery bacilli. Twenty-two months later they were still free from dysentery bacilli. A single course of treatment is inadequate in some cases. This is particularly so in children who are weak or wasted. Apart from dermatitis, occurring in 1.4% of patients, the treatment causes no complications.

 ABSTRACT : Aqueous extracts of agar cultures of a single
 microorganism possessed antitumor activity. As a
 result of chemical purification, dialysis, and
 lyophilization, the active preparation, called
 nucleoside (N) was obtained in desiccated form. Chem-
 ical studies of N showed that it is, apparently,
 a polypeptide. It is fairly stable and is practi-
 cally non-toxic for experimental animals. N sup-
 pressed the growth of adenocarcinoma of the Har-
 dish type and of sarcoma 35 by about 50%. In ex-
 periments with mice the best therapeutic effect
 was produced by intravenous injection of N, while
 in experiments with rats, intraperitoneal injec-
 tion

Title : Oscillations of a Space Charge Cloud in a Cylindrical Magnetron

Orig Pub : Radiotekhnika i elektronika, 1956, 1, No 2, 233-244; No 3, 344-357

Abstract : The article is devoted to a study of oscillations in a magnetron whose frequency is not related to the parameter of the resonator system. In the first part, the energy method is used to determine the condition under which the static state of the electron cloud becomes unstable upon appearance of a synchronous layer. It is shown that the well-known Hartree function determines the natural frequencies of the electron cloud and its dynamic stable limit. A diagram is obtained for determining the possible spectrum of the oscillations of the space charge cloud. The effect of dispersion of the waves on the spectrum of the oscillations is steady. It is established that the dispersion of the waves in the electron stream leads to a limitation of the spectrum of the

excited frequencies and to a deviation from the Hartree formula, a deviation which increases with the diminishing number of the type of oscillation. An experimental investigation of the oscillations of the electron cloud have been carried on the series of multi-resonator magnetrons with cathodes of various types (tungsten direct-heated, tantalum, and indirectly-heated oxide cathodes). The apparatus and the experimental procedure are described. Oscillograms are given for the oscillation zones and for their spectral composition. The common features of the behavior of the oscillations in different magnetrons, regardless of the difference in their construction and dimensions, are pointed out. The existence of dispersion of the waves in the electron beam is experimentally confirmed. The periodic structure of the oscillation zones is established. The results of the experiments are in good agreement with the theoretical derivations of the first part of the article. Bibliography, 20 titles.

TITLE: Experimental Investigation of Ferrite Amplifier

PERIODICAL: Radiotekhnika i elektronika, 1960, Vol 5, Nr 2, pp 288-295 (USSR)

ABSTRACT: The subject of the present article is a report on tests of a ferrite amplifier (similar to the one M. T. Weiss, was using (see reference end of abstract) under a degenerate electromagnetic regime. A block diagram of the installation is shown in Fig. 1. A magnetron was used as a power supply for excitation, the power level of which was controlled by a thermistor bridge. Its signal was used by the sem-automatic recorder of the power absorption spectrum in the ferrite at excitation frequency. A pulse klystron oscillator was the source of the amplified pulse signal. The relations measured during the tuning of the ferromagnetic amplifier are shown in Fig. 2.

The relation $f_m = 2f_{\text{res}}(H_0)$ was maintained with the aid of a spectrum analyzer. For a more effective excitation of the amplifier by the magnetron, a study of power absorption in the system at the excitation frequency was required. Typical curves are shown in Figs. 4 and 5.

Fig. 5. Curves of power absorption by ferrite at excitation frequency (magnetron level) (disc 3.8 x 1mm).

It was expected that there would be no noticeable increase in precession angle of magnetization. The experiment proved the opposite. A typical graph (see Fig. 7) shows that precession angle θ calculated according to equation

$$\theta = \frac{h}{2\Delta H} \approx \frac{0.103 \sqrt{P}}{2\Delta H},$$

increases by 2.5 times above the threshold. This permitted a selection of the working point of the power amplifier considerably above the threshold where the resonance curve starts widening. This lowers the demands from the ferrite element.

The pulse from the klystron oscillator passing at the time of a powerful magnetron pulse showed a flare as it appears in Fig. 8.

Fig. 8. Pulse of amplified signal on oscillograph screen.

It was found that this flare is not due to tuning or direct passage of excitation power, but is a pulse at signal frequency f_s . The amplification coefficient was measured, and at a 3 db level its dependence on excitation power is shown on Fig. 9. The parametric character of ferrite amplifier was proven by the

One of the ferrite amplifiers was operated as an oscillator and was used as a signal pulse source at frequency $f_m/2$ synchronized with the magnetron. The second device was fed by the same magnetron, underexcited and operated as an amplifier of the first device (see Fig. 11).

phase relations: (1) magnetron; (2) ferrite oscillator;
(3) phase shifter; (4) ferrite amplifier; (5) filter;
(6) detector; (7, 8) attenuators.

When phase φ of the amplified signal changed at the
amplifier input, a periodic change in output power
was observed. A similar dependence was observed at
the change of signal excitation phase. This confirms
the parametric theory of ferrite amplifiers. Con-
clusions: (1) Ferrite amplifiers of regenerative
type have a relatively narrow frequency band ($< 0.1\%$),
decreasing with an increased amplification. (2)

card 13/15

Experimental Investigation of Ferrite
Amplifier

SCV/100-6-2-14/26

Relatively high threshold power imposed a pulse regime. A continuous regime may be possible with better cooling. (3) The amplifier operation as described ($f_s = f_m/2$) shows a phase dependence of amplification.

A semistatic operation or work under nonresonant electromagnetic conditions eliminates this drawback.

(4) The parametric theory of ferrite amplification admits in principle an operation at an excitation frequency lower than that of the signal $f_s = n/2 f_{exc}$

when $n > 2$; however, this requires a considerable increase in excitation power and is impractical. A. I. Popova supplied ferrite monocrystals. There are 12 figures; and 12 U.S. References. TITLE: Experimental Investigation of the Degenerate Regime of
a Ferrite Amplifier

PERIODICAL: Radiotekhnika i elektronika, 1960, Vol 5, Nr 6,
pp 943-954 (USSR)

ABSTRACT: The theory developed by Mandel'shtam, Papaleksi, Divil'kovskiy and Rytov is employed to describe the characteristics of a ferrite amplifier in the degenerate electromagnetic regime. Such an amplifier was proposed by Suhl (Refs 1-3) and constructed by Weiss (Ref 7). At no time did Weiss and others compare the experimental results with the theoretical predictions. Suhl's quasi-linear theory neglects the effect of higher order non-linear magnetisation terms on the amplifier operation and neglects the phase relations between the amplified signal and the excitation, which are essential for the degenerate electromagnetic regime. This analysis is the purpose of the present article. The experimental system permitted the exact realisation of the condition that the pumping frequency is twice the signal frequency.

Experimental Investigation of the Degenerate Regime of a Ferrite Amplifier

The following partially inter-related questions were studied: determination of the oscillation threshold of the ferrite amplifier and its dependence on the loaded Q of the resonator; the dependence of gain on the excitation power at the most favorable and least favorable phases for operation in reflection; the dependence of amplification and bandwidth on excitation power at random phase in operation in transmission; the dependence of amplification on the phase angle in transmission; comparison of the transmission and reflection loads of the amplifier. Generally good agreement between experimental and theoretical values is obtained, except in the neighbourhood of limiting values of VSWR where parasitic reflections, losses and other forms of non-idealness of the measurement channel have substantial influence. Certain higher-order non-linear effects, outside the scope of the quasi-linear ferrite amplifier theory are noted. At excitation powers somewhat lower than threshold weak oscillations begin. The finite amplitude of oscillation indicates the

presence of non-linear attenuation terms. The oscillation frequency differs from the optimal frequency of amplified signal at high gain factors (close to the oscillation threshold) and the optimum values of magnetic fields for oscillation and amplified signal do not coincide. These phenomena are ascribed to the effects of signal detection at high amplitudes which causes a change in the longitudinal magnetisation component and a shift in the resonant magnetic field value. At low oscillation amplitudes detection does not occur. A monotonic change of resonant value of magnetic field with increase of excitation power indicates strong detection effects. There are 10 figures and 11 references, of which 4 are Soviet, 7 English.

PROLOG: This book is intended for engineers.

CONTENTS: The book contains 29 articles dealing with professional work performed
by mechanical engineers, such as the calculation of shells, rods, and plates,
and solutions of problems in stress distribution and equilibrium. Oscillations
(including plates) and determination of shells, equilibrium of shells, plates,
rods and shells, stability of rods, plates, frames and other members, stress
concentration, and bending are discussed. Oscillations of elements of
any material. Abstracts accompany each article.

AUTHOR: Derkachev, A.A.

TITLE: The determination of the least characteristic number of a matrix the elements of which are polynomials of the parameter λ

PERIODICAL: Referativnyy zhurnal. Matematika, no.3, 1960, 158, abstract 3477. (Tr. Novocherk. politekhn. in-ta, 1958, 57/71, 19-25)

TEXT: For the system of equations

$$X = (\lambda A_1 + \lambda^2 A_2 + \dots + \lambda^m A_m)X + Y, \quad (1)$$

where X -- vector in the n -dimensional space, A_1, \dots, A_m -- quadratic matrices of n -th order, the parameter λ is chosen so that (1) has a solution different from zero. With the aid of the iteration method the author determines the least characteristic number λ_1 . Seeking the solution in the form $X = Y_0 + \lambda_1 Y_1 + \lambda_1^2 Y_2 + \dots$ then $Y_0 = Y$, $Y_1 = A_1 Y_0$, $Y_2 = A_1 Y_1 + A_2 Y_0, \dots, Y_k = A_1 Y_{k-1} + A_2 Y_{k-2} + \dots + A_{k-1} Y_0$. Then λ_1 is found

Card 1/2

The determination of the least...

26635
S/044/60/000/003/007/012
C111/C222

according to the formula

$$\lambda_1 = \lim_{k \rightarrow \infty} \frac{y_k^{(i)}}{y_{(k-1)}^{(i)}}$$

where $y_k^{(i)}$ and $y_{(k-1)}^{(i)}$ are the i -th components of the vectors Y_k and Y_{k-1} .

For the eigenvector X_1 belonging to λ_1 one obtains:

$$X_1 \approx Y_k.$$

The author shows that for systems (1) with a great number of unknowns this method is more profitable than the graphical method.
